Atomic Scale Characterization and Manipulation Laboratory. Location: Bldg. 220, Rm. B48. Future generations of electronics, information processing, and data storage technologies will be based on nanoscale elements with unusual properties that will enable innovative device capabilities. To harness the potential of nanotechnology, measurement tools and methods are needed that can not only characterize nanostructures at the atomic scale, but create them with atomic precision.

Characterization, when used in materials science, refers to the broad and general process by which a material's structure and properties are probed and measured. It is a fundamental process in the field of materials science, without which no scientific understanding of engineering materials could be ascertained.

Abstract The shear bands in a model amorphous CuZr metallic glass are examined using atomistic simulations. The localized shear zones are characterized at atomic scales by the nearest-neighbor atomic bond rotation angle, the nearest-neighbor atomic bond length, the atomic volume, and the potential energy.
