The basic objective of distillation is to take a liquid mixture and separate it into two or more streams which have compositions different to the feed stream. In a basic distillation column a feed stream enters in the middle of the column and two streams leave, one at the top and one at the bottom. Components with lower boiling points are concentrated in the stream leaving the top while components with higher boiling points are concentrated in the stream leaving the bottom.

Chapter 18 Ethanol distillation: the fundamentals

Distillation is a widely used method for separating mixtures based on differences in the conditions required to change the phase of components of the mixture. To separate a mixture of liquids, the liquid can be heated to force components, which have different boiling points, into the gas phase.

A split represents separation of a mixture into two product streams. A distillation configuration is thus a collection of splits. For instance, the configuration shown in Figure 7.2(a) carries out the split ABC–A/BC, followed by BC–B/C. Such splits are referred to as sharp splits because the product streams have no (or acceptably low levels of) overlapping components.
