Pooled Time Series Analysis

Researchers have often been troubled with relevant data available from both temporal observations at regular intervals (time series) and from observations at single points of time (cross section). Pooled Times Series Analysis combines time series and cross- sectional data to provide the researcher with an efficient method of analysis and improved estimates of the population being studied.

Time series observations are hard to analyze mainly because of the interdependency of observations over time. The basic model, $y_t = c + x_t \beta + \varepsilon_t$ ($t = 1, 2, \dots, T$), where y_t is the dependent variable and x_t is a $1 \times K$ vector of explanatory variables, has stochastic errors ε_t such that $E(\varepsilon_i / x_i) = 0$ but $\varepsilon_t = \rho \varepsilon_{t-1} + u_t$...

The use of pooled time series cross section (PTSCS) data has become ubiquitous in observational analyses across the social sciences. Even the identification revolution that swept through empirical social science in the last two decades finds some merit in using data that combines observations across units and over time, because it allows identifi-

Data definitions. Pooled data occur when we have a “time series of cross sections,” but the observations in each cross section do not necessarily refer to the same unit. Section 8 Models for Pooled and Panel Data

Time series analysis is a statistical technique that deals with time series data, or trend analysis. Time series data means that data is in a series of particular time periods or intervals. The data is considered in three types: Time series data: A set of observations on the values that a variable takes at different

Pooled data is a mixture of time series data and cross-section data. One example is GNP per capita of all European countries over ten years. Panel, longitudinal or micropanel data is a type that is pooled data of nature. The difference is that we measure over the same cross-sectional unit for individuals, households, firms, etc.
